Dose-Efficient Imaging

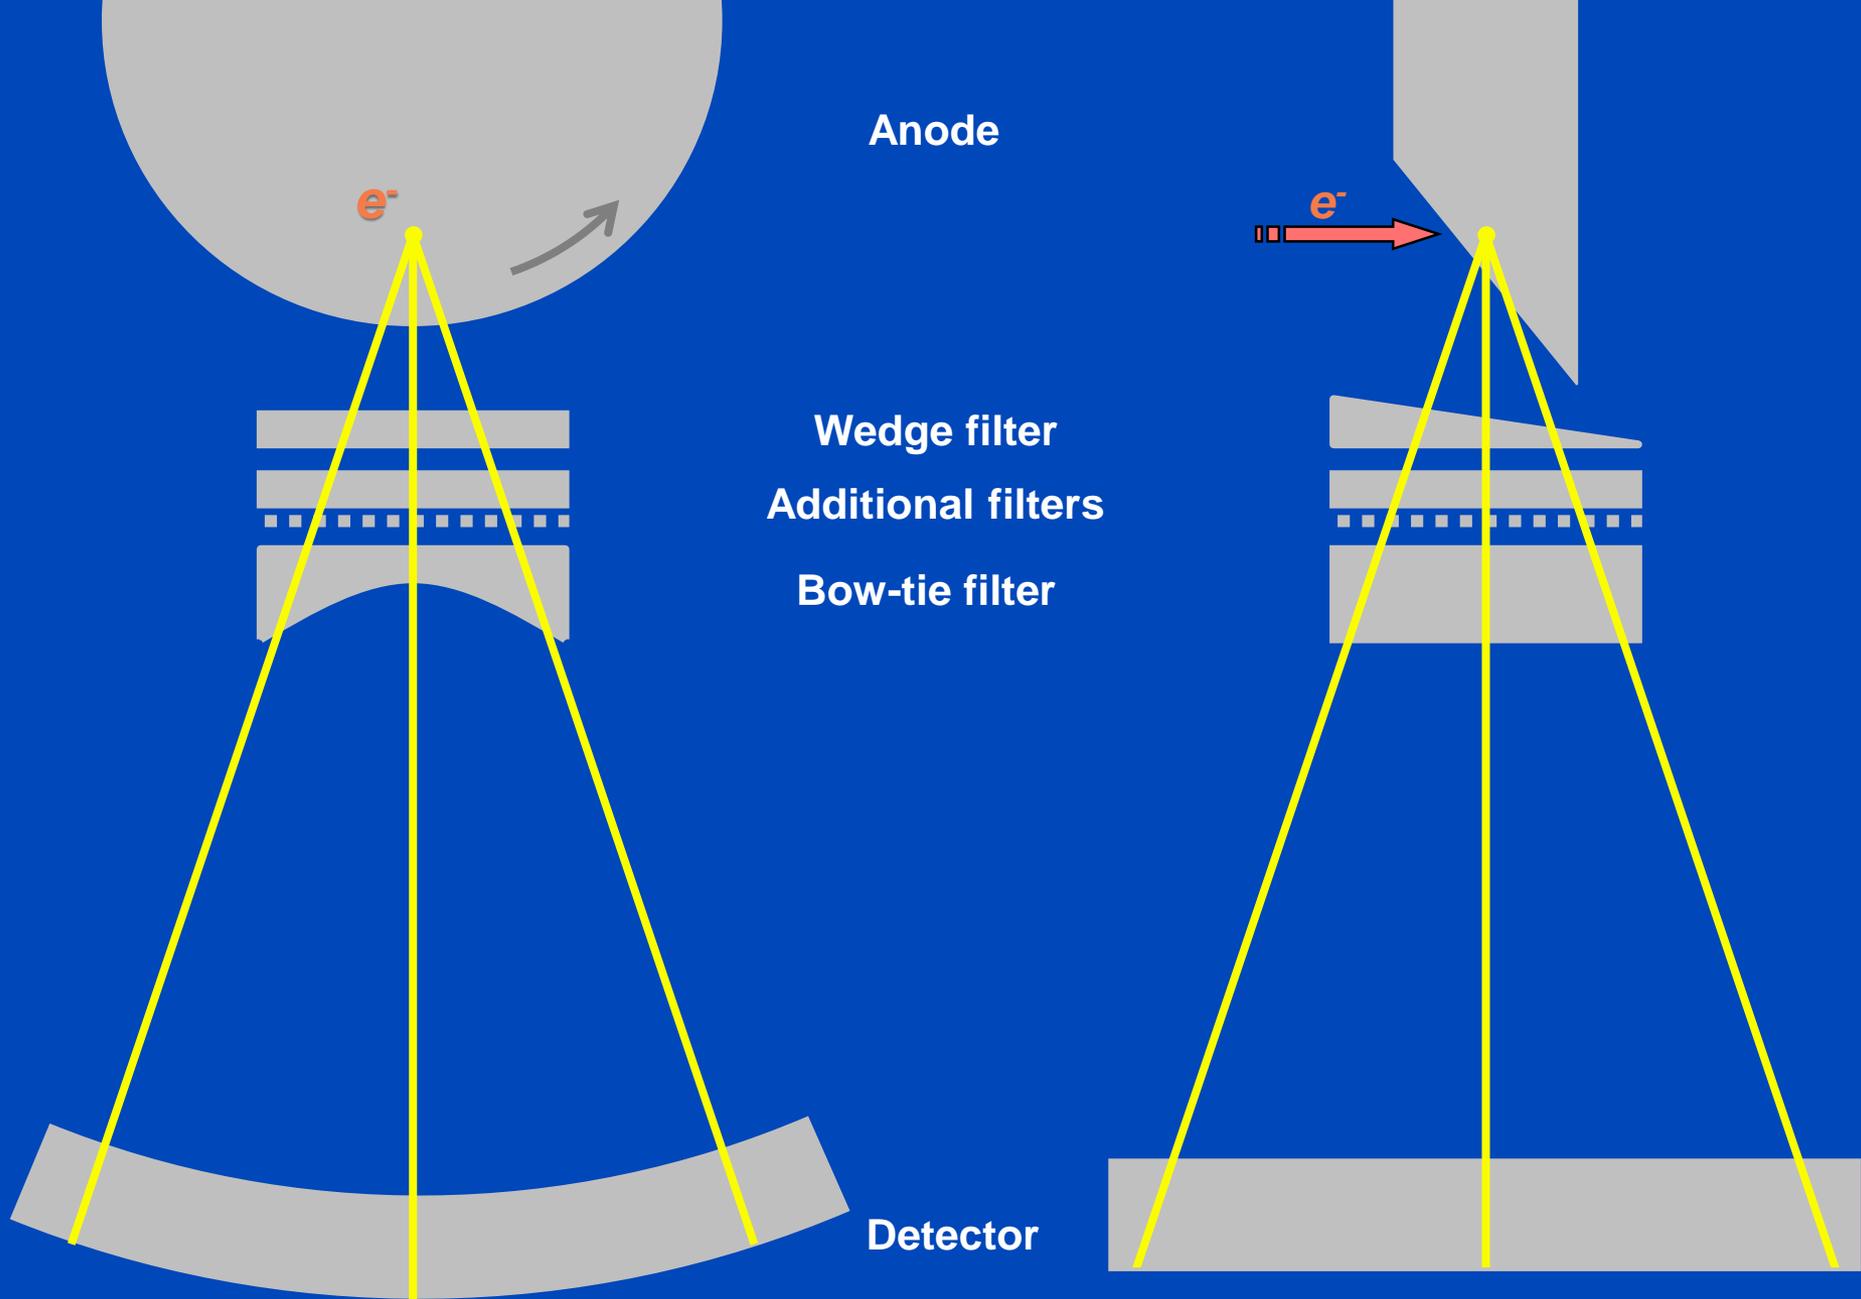

Figure not drawn to scale. Type and order of prefiltration may differ from scanner to scanner. Depending on the selected protocol filters are changed automatically (e.g. small bowtie for pediatric scans).

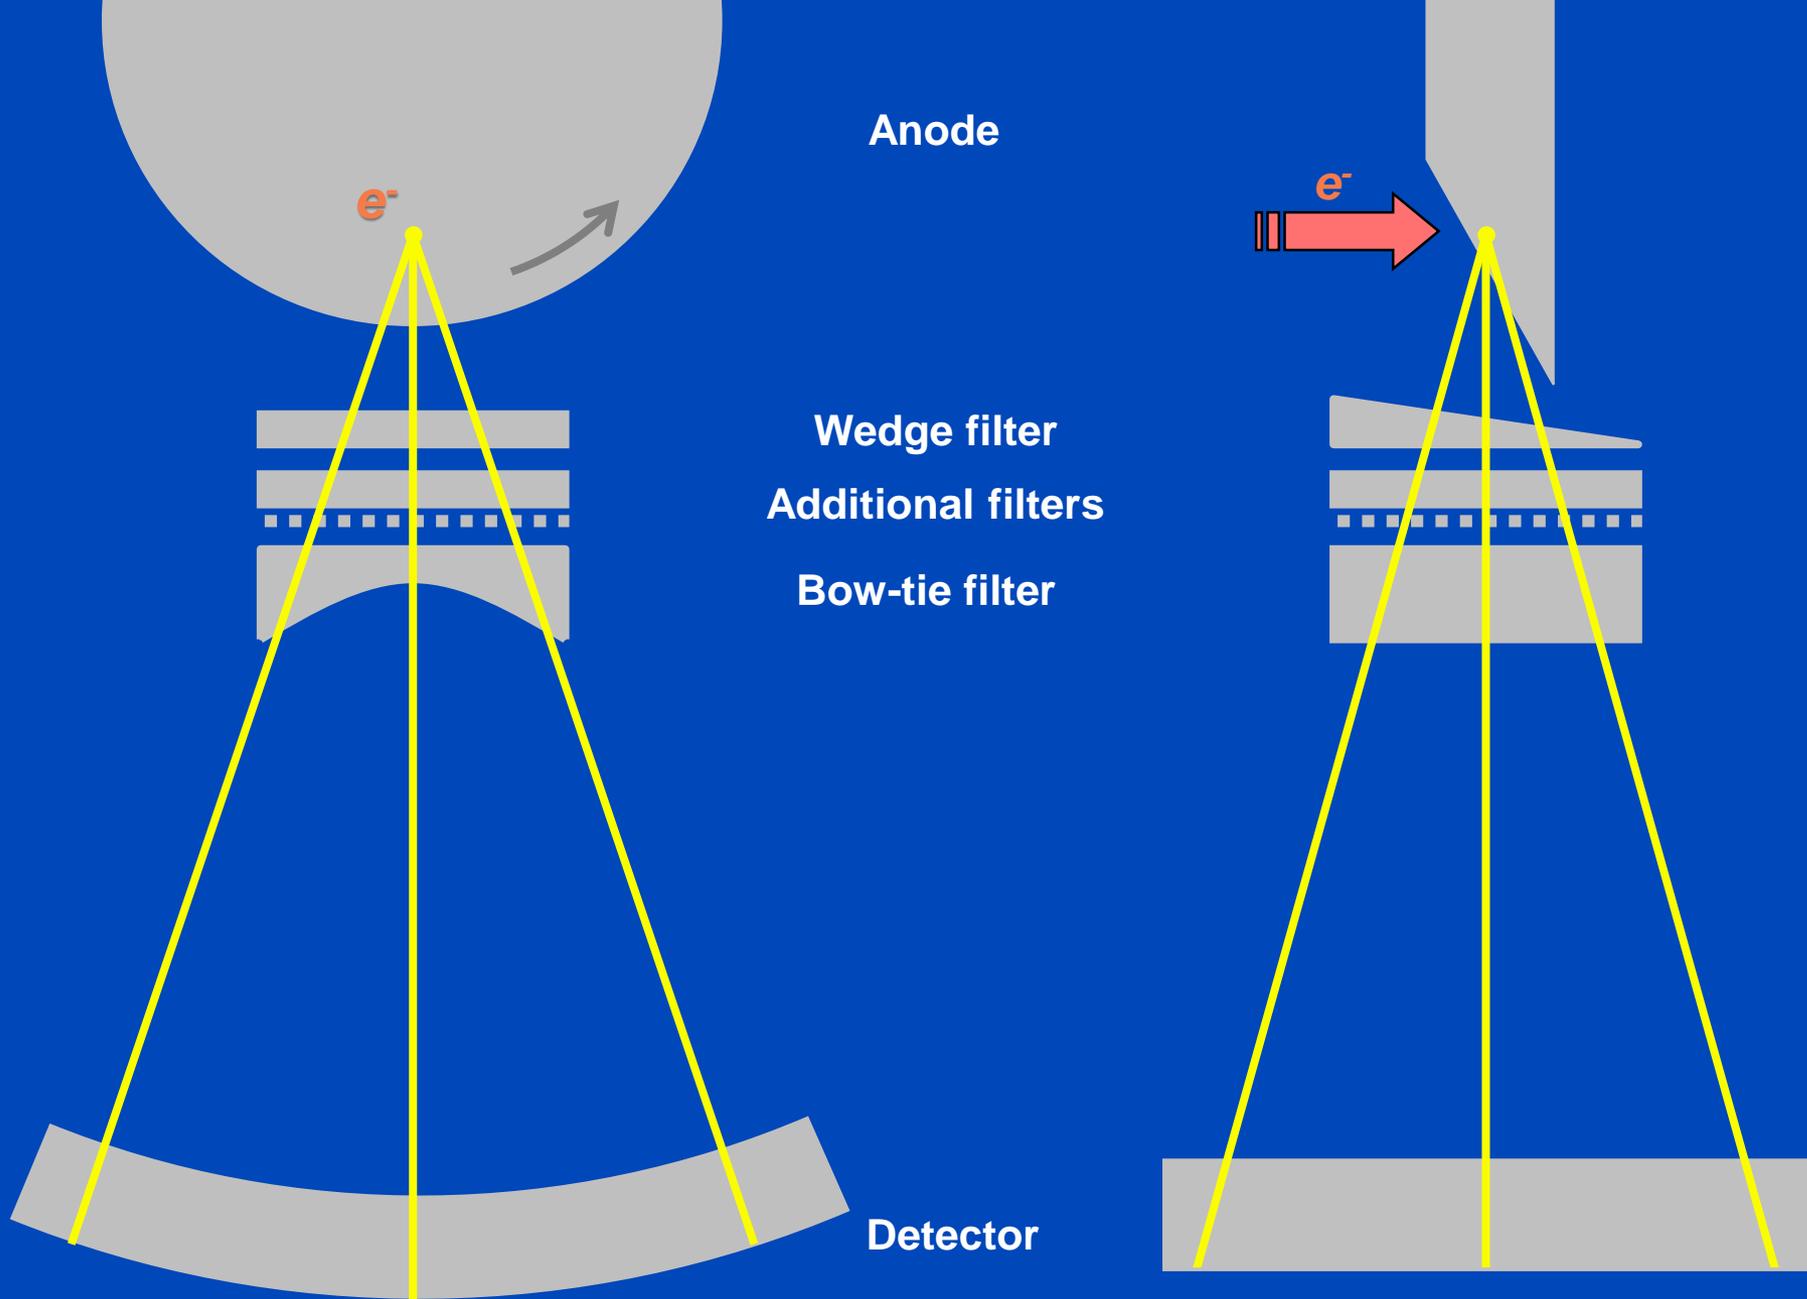

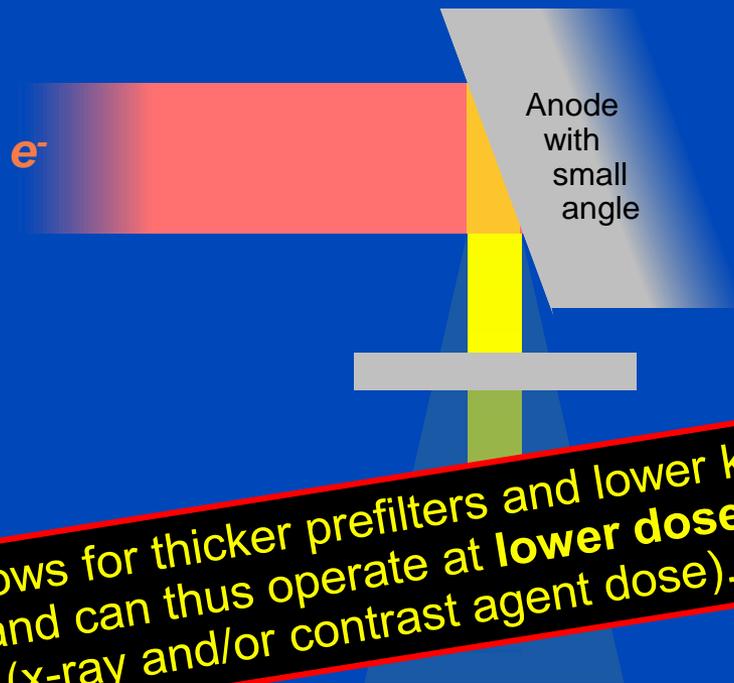

Figure not drawn to scale. Type and order of prefiltration may differ from scanner to scanner. Depending on the selected protocol filters are changed automatically (e.g. small bowtie for pediatric scans).

Narrow Cone

=

High Tube Power

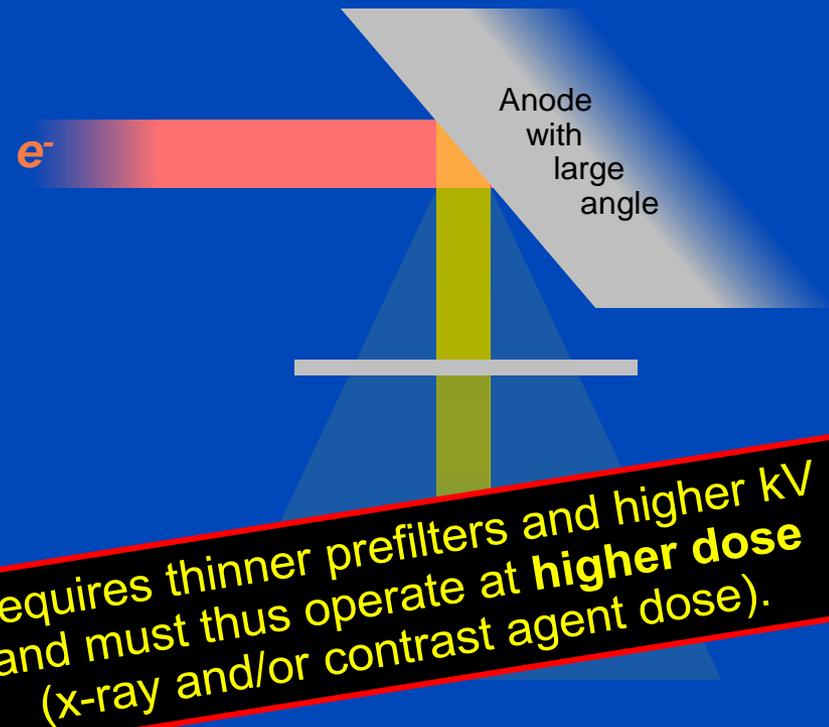

Allows for thicker prefilters and lower kV and can thus operate at **lower dose** (x-ray and/or contrast agent dose).

Wide Cone

=

Low Tube Power

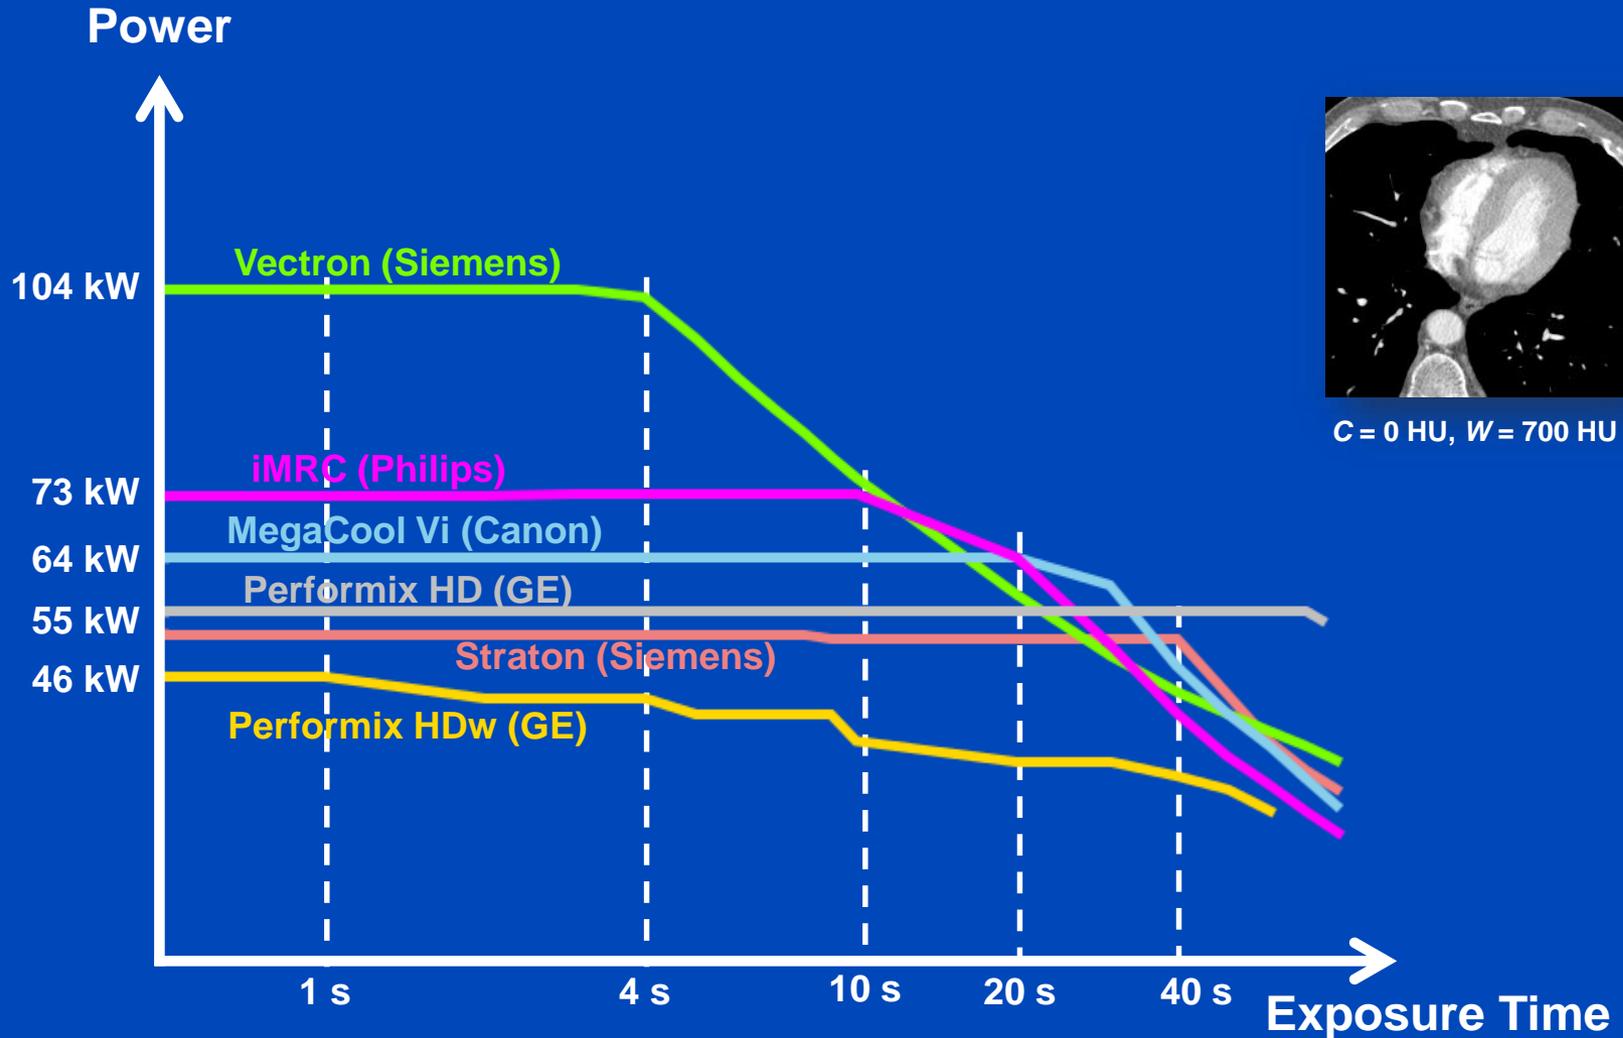

Requires thinner prefilters and higher kV and must thus operate at **higher dose** (x-ray and/or contrast agent dose).

... at the same spatial resolution

Tube Voltage 120 kV

Bowtie Filter

- Also known as shaped filter or as form filter
- Static filter to optimize the intensity profile through a rotationally symmetric isocentered object $\mu(r)$ of typical shape, e.g. a disk
- Often optimized to either
 - be **good for the detector**, i.e. to yield a constant signal (e.g. energy-weighted intensity) at the detector,
 - or to be **good for the patient**¹, i.e. to yield the minimal patient dose at given image quality.

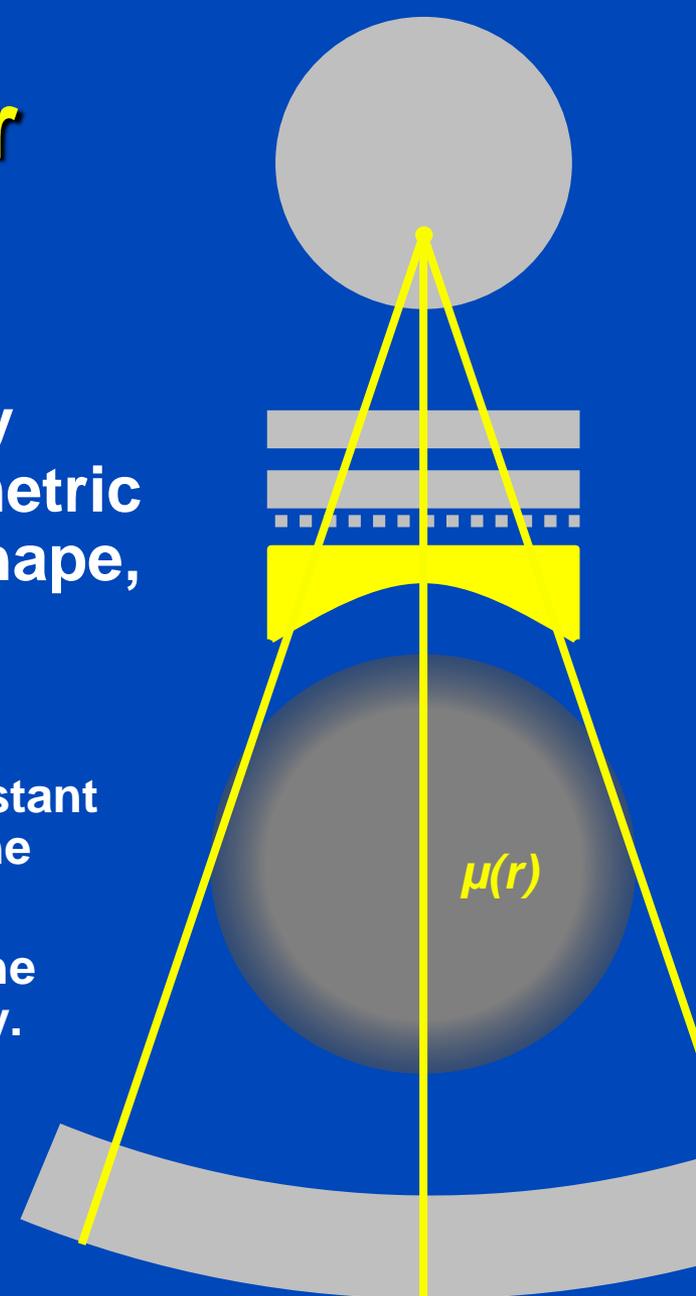

Figure not drawn to scale.

Bowtie Filter

$$p(\xi) = R\mu(r)$$

- **Good for the detector:**

- Radiation incident on the detector: $I(\xi) = I_0(\xi)e^{-p(\xi)} = c$
- Radiation incident on the object: $I_0(\xi) = ce^{p(\xi)}$
- Required form filter thickness: $d(\xi) = d_0 - p(\xi)/\mu_{\text{bowtie}}$

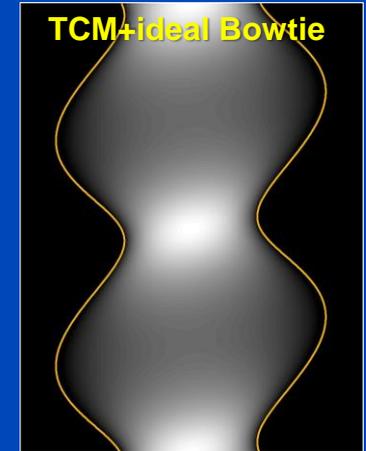

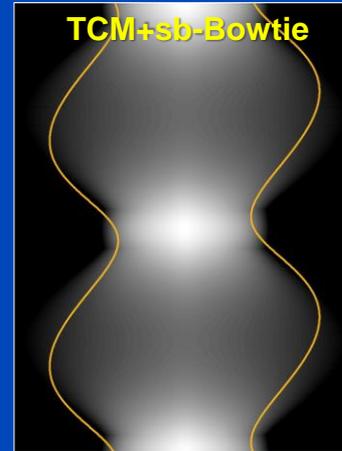

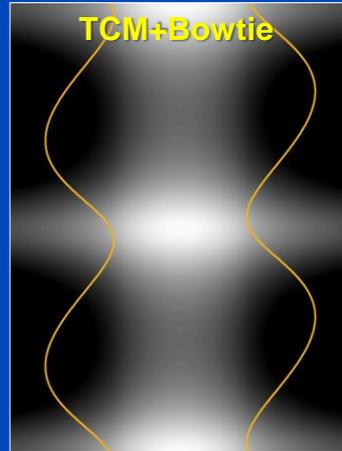

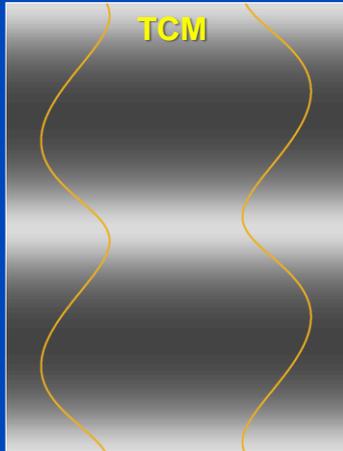

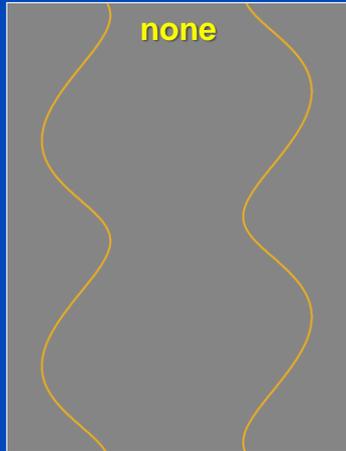

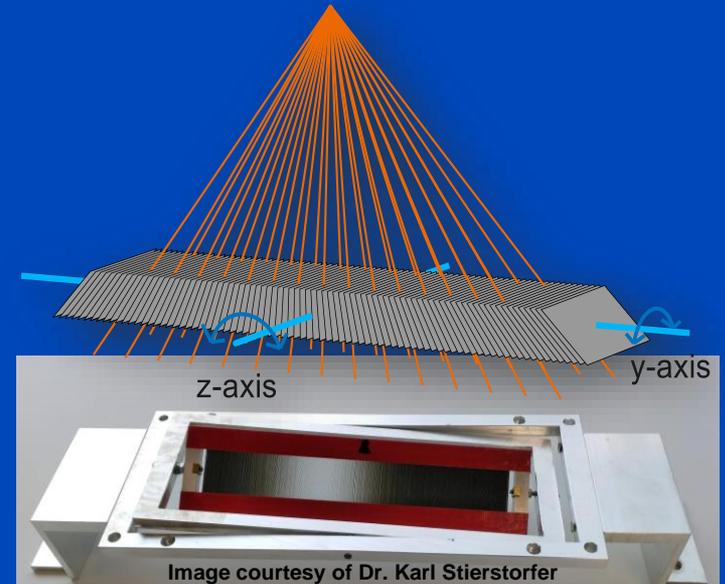

- **Good for the patient:**

- Minimal noise at constant dose: $\int d\xi (\sigma^2(\xi) + \lambda I_0(\xi))$ with $\sigma^2(\xi) = \frac{e^{p(\xi)}}{I_0(\xi)}$
- Radiation incident on the object: $I_0^2(\xi) = ce^{p(\xi)}$
- Required form filter thickness¹: $d(\xi) = d_0 - \frac{1}{2}p(\xi)/\mu_{\text{bowtie}}$

¹Michael D. Harpen. A simple theorem relating noise and patient dose in computed tomography. Med. Phys. 26(11):2231-2234, November 1999

Photon Counting

Indirect Conversion (Today)

i.e. max $O(40 \cdot 10^3)$ cps

Direct Conversion (Future)

i.e. max $O(40 \cdot 10^6)$ cps

Requirements for CT: up to 10^9 x-ray photon counts per second per mm^2 .
Hence, photon counting only achievable for direct converters.

Readout Modes of the Siemens CountT

Macro Mode

0.9 × 1.1 mm focus
1×2 readouts

12	12	12	12

No FFS on detector B (photon counting detector). 4×4 subpixels of 225 μm size = 0.9 mm pixels (0.5 mm at isocenter). An additional 225 μm gap (e.g. for anti scatter grid) yields a pixel pitch of 1.125 mm. The whole detector consists of 128×1920 subpixels = 32×480 macro pixels.

2	2	2	2
2	2	2	2
2	2	2	2
2	2	2	2

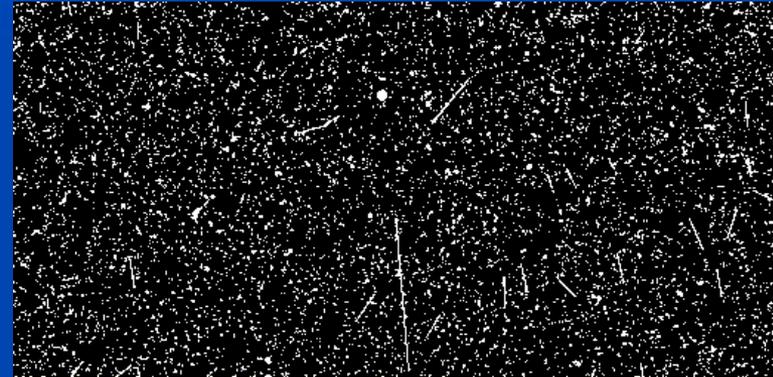

This photon-counting whole-body CT prototype, installed at the Mayo Clinic, at the NIH and at the DKFZ is a DSCT system. However, it is restricted to run in single source mode. The second source is used for data completion and for comparisons with EI detectors.

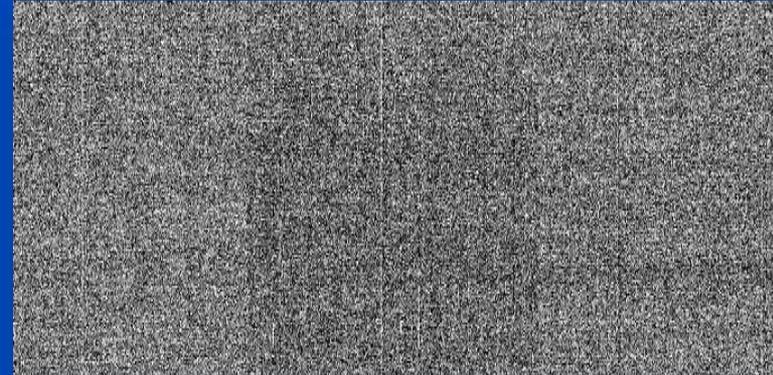

Potential Advantages of Photon Counting CT

- **No electronic noise**
 - Less dose for infants
 - Less noise for obese patients
- **Counting**
 - Swank factor = 1 = maximal
 - Higher weights on low energies = good for iodine contrast
- **Energy bin weighting**
 - Lower dose/noise
 - Improved iodine CNR
- **Smaller pixels (to avoid pileup)**
 - Higher spatial resolution
 - Lower dose/noise at conventional resolution
- **Spectral information on demand**

Photon counting (x-ray off, 5 min/frame)

Energy integrating (x-ray off, 5 min/frame)

Sensor Dose Efficiency

	Clinical CT (120 kV)			Flat Detector CT (120 kV)			Photon Counting CT (120 kV)		
Material	Gd ₂ O ₂ S			CsI			CdTe		
Density	7.44 g/cm ³			4.5 g/cm ³			5.85 g/cm ³		
Thickness	1.4 mm			0.6 mm			1.6 mm		
Manufacturer	Siemens			Varian			Siemens CounT		
Water Layer	0 cm	20 cm	40 cm	0 cm	20 cm	40 cm	0 cm	20 cm	40 cm
Photons absorbed	96.2%	92.7%	89.8%	73.5%	59.2%	53.9%	94.5%	88.2%	83.1%
Energy absorbed	94.3%	90.7%	87.9%	66.4%	53.9%	46.6%	91.2%	84.8%	79.9%

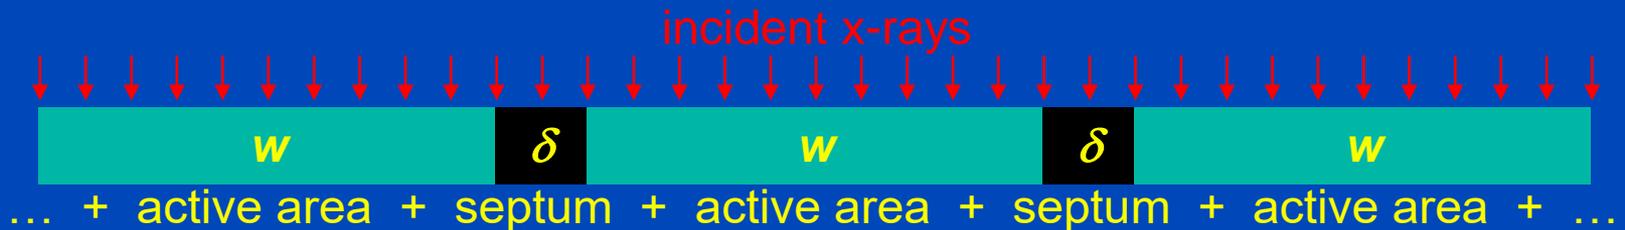

Absorption values are relative to a detector of infinite thickness.

System Model

- Object $f(x)$
- Presampling function $s(x)$, normalized to unit area
- Algorithm $a(x)$, normalized to unit area
- Image $g(x)$ with

$$g(x) = f(x) * s(x) * a(x) = f(x) * \text{PSF}(x)$$

- Example:

$$s(x) = \Pi_d^*(x)$$

w = detector pixel width
 δ = dead space between pixels

To Bin or not to Bin?

(the continuous view)

*This nice phrase
was coined
by Norbert Pelc.*

- We have $PSF(x) = s(x) * a(x)$ and $MTF(u) = S(u)A(u)$.
- From Rayleigh's theorem we find noise is

$$N^2 = \int dx a^2(x) = \int du A^2(u) = \int du \frac{MTF^2(u)}{c^2(u)}$$

- Compare **Avoid binning, if possible!** large (B) detector pixels:

- We have $S_A(u) > S_B(u)$ and thus $N_A^2 < N_B^2$.
- This means that a desired PSF/MTF is often best achieved with smaller detectors.

To Bin or not to Bin?

(the discrete view)

- Let detector B be the 2-binned version of detector A:

$$B_{2n} = \frac{1}{2}(A_{2n} + A_{2n+1}) \quad \text{Var}B = \frac{1}{2}\text{Var}A$$

- Assume LI to be used to find in-between pixel values. Wlog we may then consider B to be unsampled with mid-point interpolation.

\hat{B}

20% more noise variance may be compensated by 20% more x-ray dose. Any alternative? Yes: **Avoid binning, if possible!** In 2D binning implies 44% more noise variance or dose. Again, the answer is: „not to bin“.

- To obtain \hat{A} we need to use a detector

$$a = \frac{1}{2} (1, 1) * \frac{1}{4} (1, 2, 1) = \frac{1}{8} (1, 3, 3, 1)$$

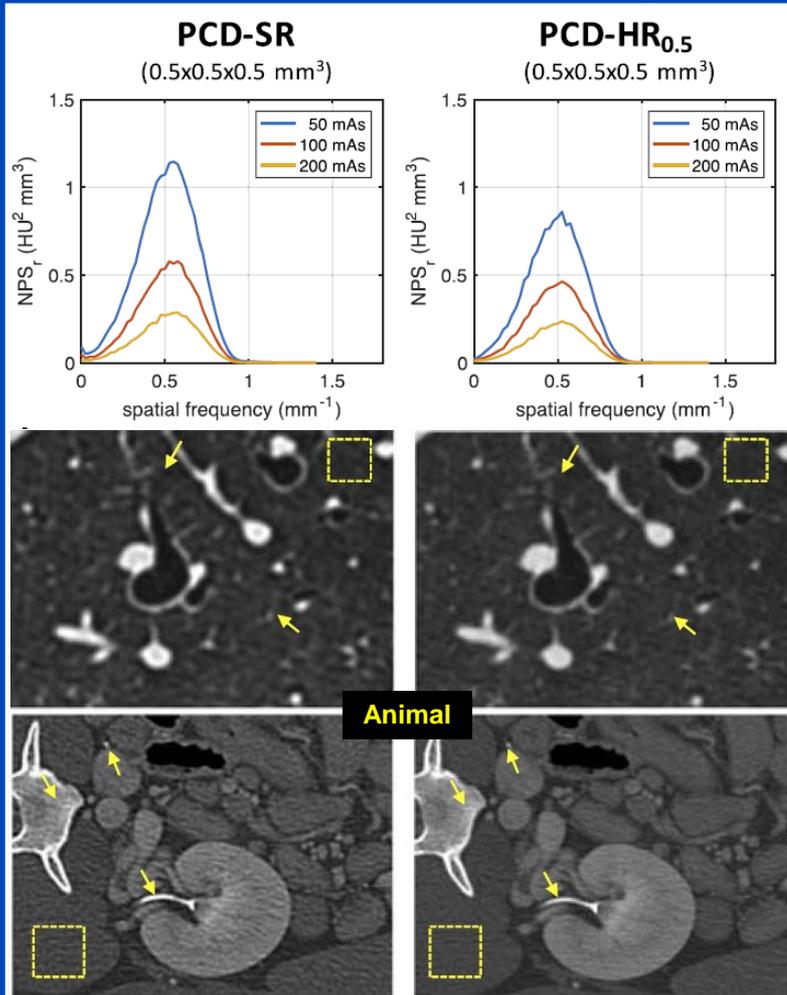

- Noise propagation yields 20% more noise (variance) for the binned detector:

$$\text{Var}\hat{A} = \frac{20}{64}\text{Var}A = \frac{5}{16}\text{Var}A$$

$$\text{Var}\hat{B} = \frac{3}{8}\text{Var}A = \frac{6}{5}\text{Var}\hat{A} = 1.2\text{Var}\hat{A}$$

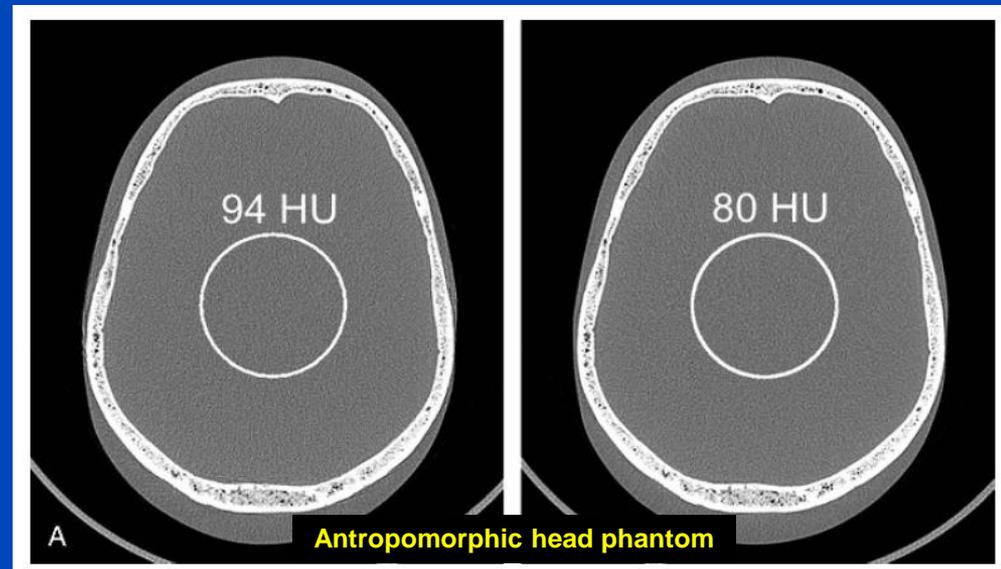

CountT Std

CountT HighRes

CountT Std

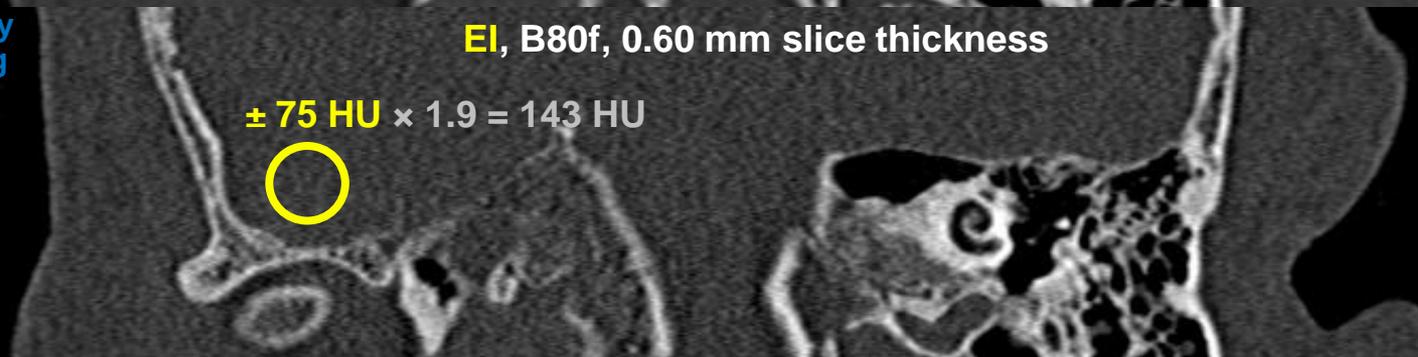

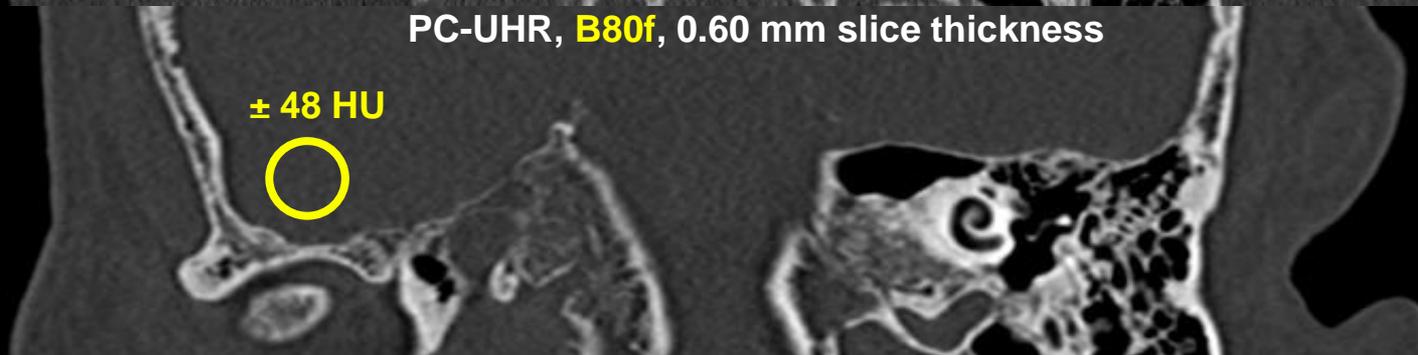

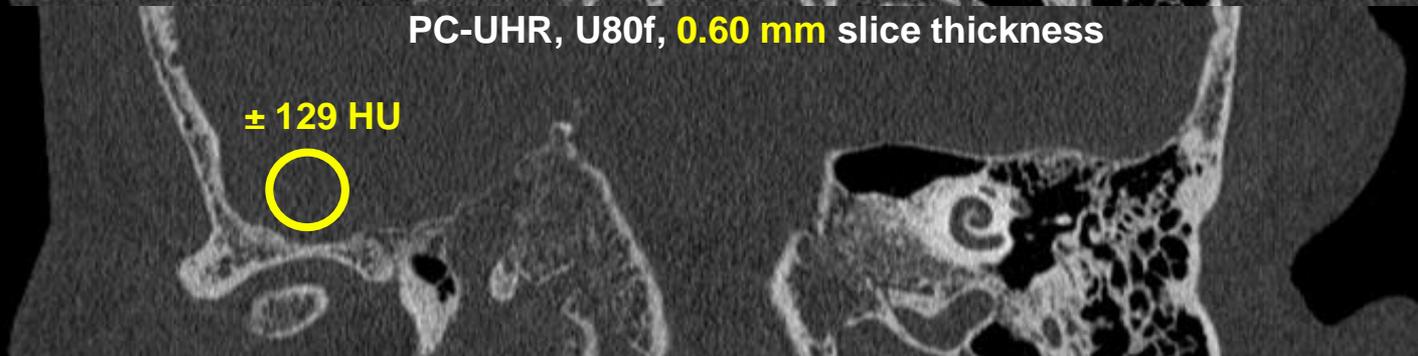

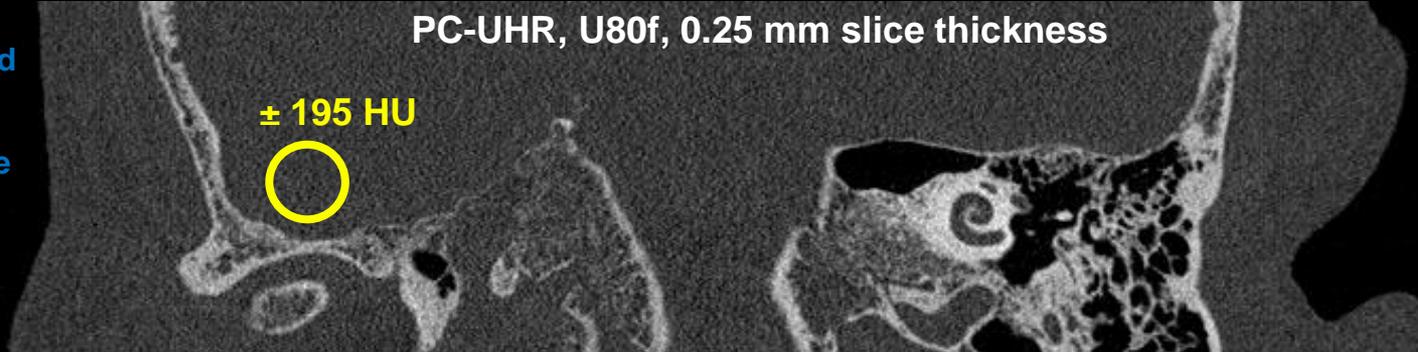

CountT HighRes

A **15% noise reduction** (from 94 HU to 80 HU) was observed (same spatial resolution and dose). This corresponds to a dose reduction of 28%.

“However, when comparing with standard resolution data at same in-plane resolution and slice thickness, the PCD 0.25 mm detector mode showed **19% less image noise** in phantom, animal, and human scans.”

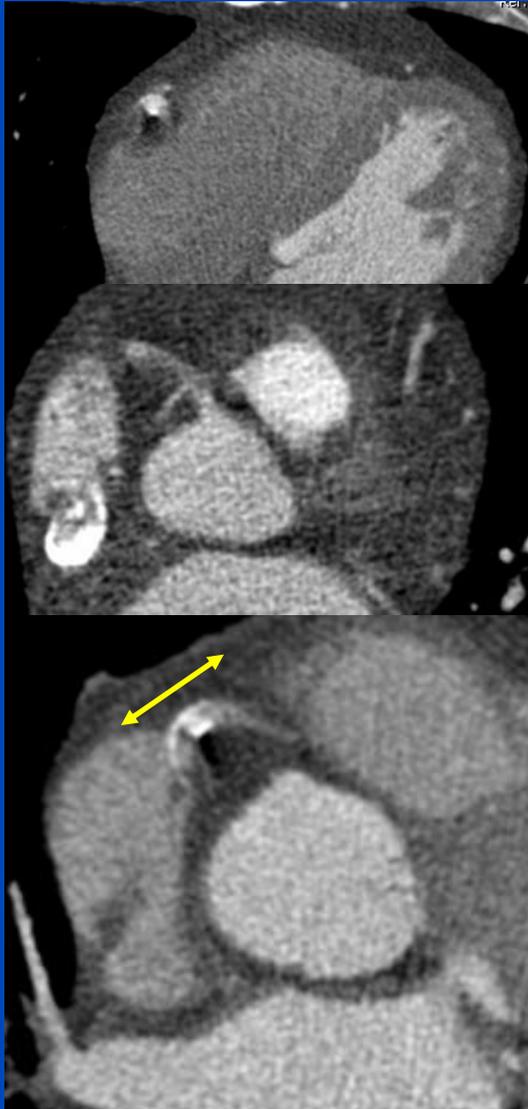

All images reconstructed with 1024^2 matrix and 0.15 mm slice increment. $C = 1000$ HU $W = 3500$ HU

Motion Compensation

Motion in Cardiac CT

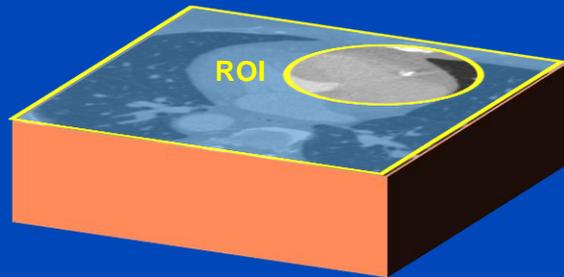

- In cardiac CT, the imaging of small and fast moving vessels places high demands on the spatial and temporal resolution of the reconstruction.
- Mean displacements of $d \approx \frac{t_{rot}}{2} \bar{v} \approx \frac{250}{2} \text{ ms} 50 \frac{\text{mm}}{\text{s}} = 6.25 \text{ mm}$ are possible (RCA mean velocity measurements^[1,2,3,4]).
- Standard FDK-based cardiac reconstruction might have an insufficient temporal resolution introducing strong motion artifacts.

PAMoCo

Generate $2K+1$ Partial Angle Reconstructions

Initial segmented stack volume

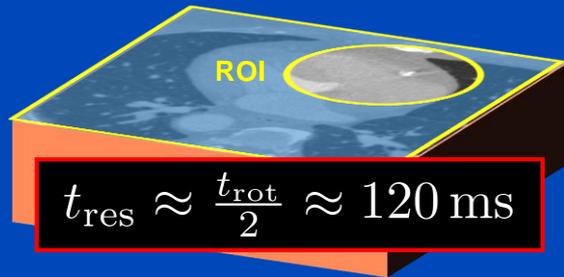

Subdivide the projection data $p'(\vartheta, \xi)$
into $2K + 1$ overlapping sectors

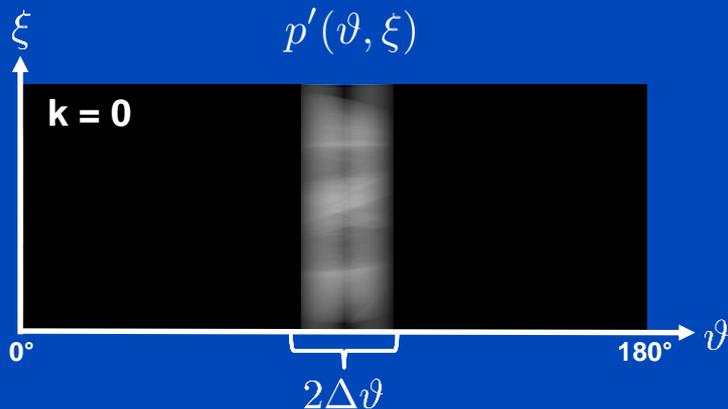

PAMoCo

Generate 2K+1 Partial Angle Reconstructions

Initial segmented stack volume

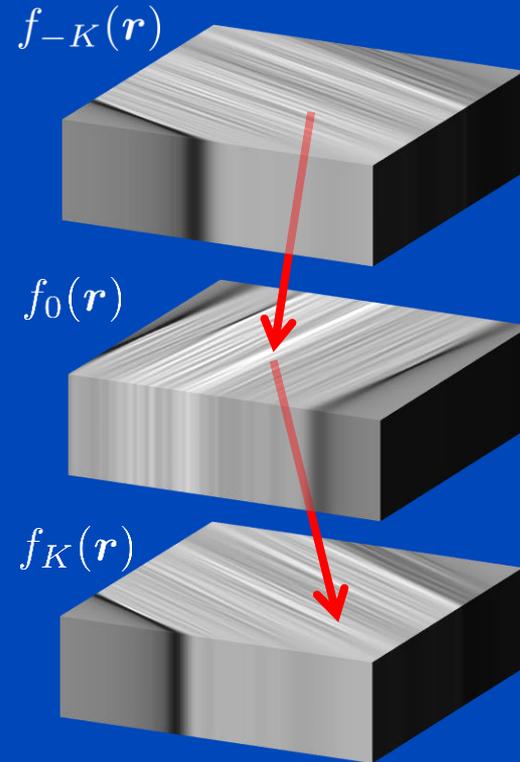

Subdivide the projection data $p'(\vartheta, \xi)$ into $2K + 1$ overlapping sectors

$$p_k(\vartheta, \xi) = w_k(\vartheta)p'(\vartheta, \xi)$$
$$w_k(\vartheta) = \Lambda((\vartheta - \vartheta_k)/2\Delta\vartheta)$$

Partial angle reconstructions $f_k(\mathbf{r})$

$$t_{\text{res}} \approx \frac{t_{\text{rot}}/2}{(2K+1)/2} \approx 10 \text{ ms}$$

$$\text{FWHM} = \Delta\vartheta$$

$$K = 12$$

PAMoCo Motion Model

- Control points along coronary arteries

$$\mathbf{r} = \mathbf{r}(\lambda_n)$$

- Polynomial around each control point

$$\mathbf{d}(\mathbf{s}, \lambda, t) = \sum_{p,l} \mathbf{s}_{lp} (\lambda - \lambda_0)^l (t - t_0)^p$$

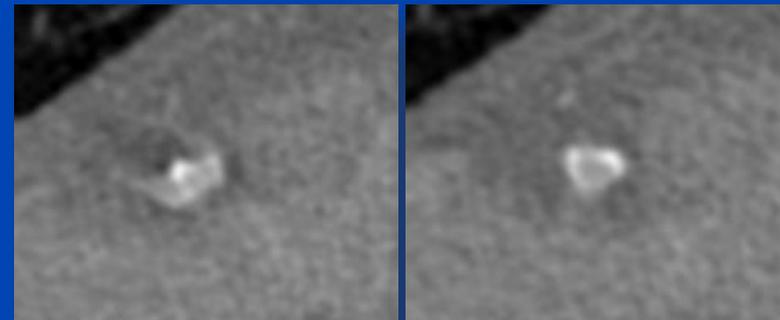

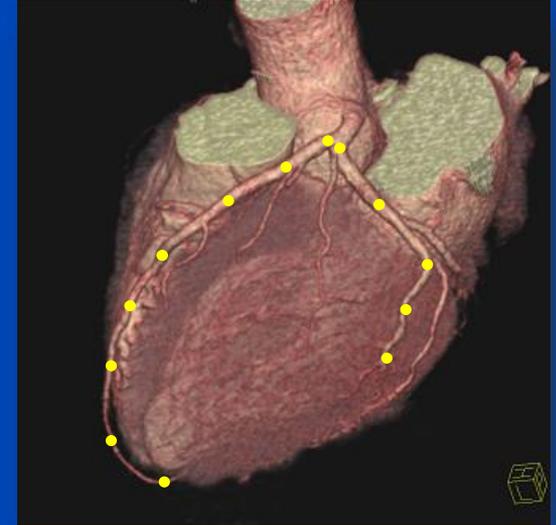

- DVFs continued onto all voxels

$$\mathbf{d} = \mathbf{d}(\mathbf{s}, \mathbf{r}, t)$$

- Sum up partial angle images

$$f_{\text{MoCo}}(\mathbf{r}) = \sum_{k=-K}^K f_k(\mathbf{r} + \mathbf{d}(\mathbf{s}, \mathbf{r}, t_k))$$

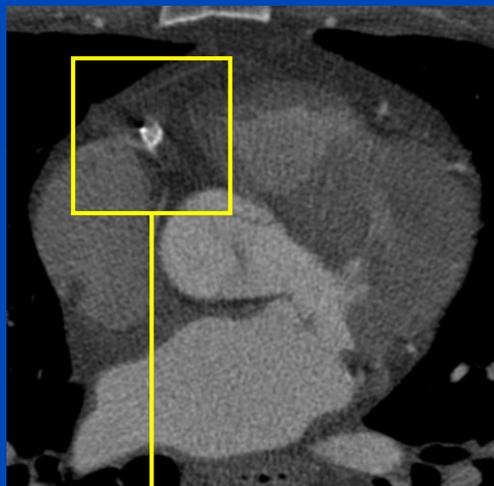

- Open DVF parameters chosen to minimize the image entropy

Real-Time Scatter Estimation (also for truncated Data)

To learn why MC fails at truncated data and what significant efforts are necessary to cope with that situation see [Kachelrieß et al. Effect of detruncation on the accuracy of MC-based scatter estimation in truncated CBCT. Med. Phys. 45(8):3574-3590, August 2018].

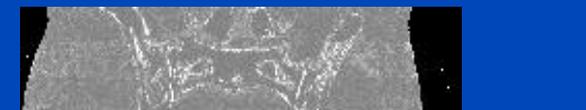

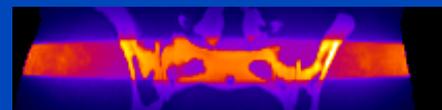

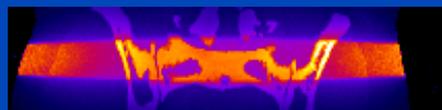

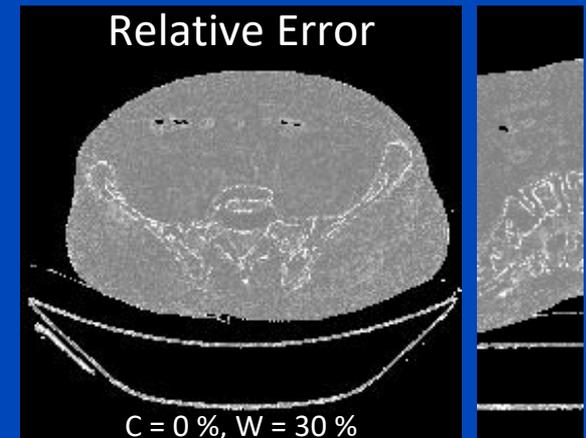

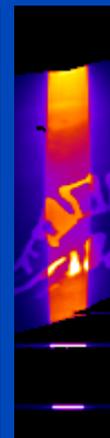

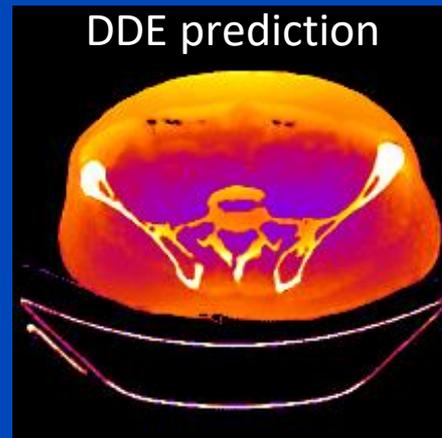

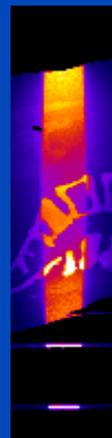

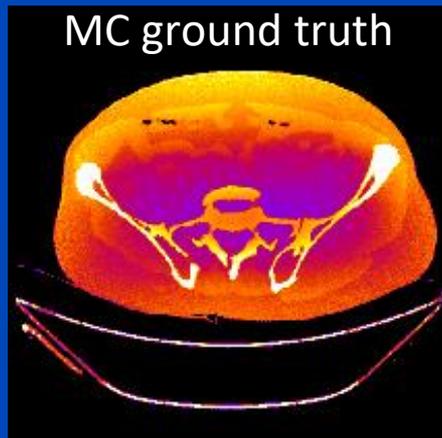

Real Time Dose Estimation

	MC	DDE
48 slices	1 h	0.25 s
whole body	20 h	5 s

MC uses 16 CPU kernels
DDE uses one Nvidia Quadro P600 GPU

DDE training took 30 h for 200 epochs,
720 samples, 48 slices per sample

Talks in this Session

1. A Flexible Iterative Reconstruction Framework for Low Dose CT (Lyu et al.)
2. Quantitative Prior-Image-Based CT Reconstruction with Mismatched Prior (Zhang et al.)
3. Noise Reduction in CT Image Using Prior Knowledge Aware Iterative Denoising (Tao et al.)
4. Dependence of Scatter-To-Primary Ratio On X-Ray Energy (Whiting et al.)
5. Effect of Multi-Slit Collimator Motion On SparseCT Image Quality for Low-Dose CT Examinations (Chen et al.)
6. Synthetic MRI-Aided Prostate Segmentation in CT Image (Lei et al.)
7. Non-Rigid 4D-CT Image Registration Using An Unsupervised Deep Convolutional Neural Network (Lei et al.)
8. Respiratory Adaptive Computed Tomography (REACT) Reduces 4DCT Imaging Artifacts Through Prospective Gating: First Experimental Results (Morton et al.)
9. Impact of Radiation Dose on Quantification Accuracy of Penumbra and Infarct Core Volume in CT Brain Perfusion (Browne et al.)
10. A Method for Automated Repeat/Reject Rate Analysis in CT (Rose et al.)

Thank You!

The 6th International Conference on Image Formation in X-Ray Computed Tomography

August 3 - August 7 • 2020 • Regensburg • Germany • www.ct-meeting.org

Conference Chair: **Marc Kachelrieß**, German Cancer Research Center (DKFZ), Heidelberg, Germany

This presentation will soon be available at www.dkfz.de/ct.
Job opportunities through DKFZ's international Fellowship programs (marc.kachelriess@dkfz.de).
Parts of the reconstruction software were provided by RayConStruct® GmbH, Nürnberg, Germany.
